## 1. Practical Examples using the RAIN Alliance ISO Numbering System

Use of access or kill passwords, user memory, locking, permalocking, and other advanced RAIN RFID features are not covered in this document. In most cases, these additional tag features do not impact selection of a numbering system.

## Example 1:

I have an existing barcode-based asset tracking system that uses a prefix of 4 letters, follow by 6 numbers. These assets never leave my organization, there are 10,000 of them currently and I add ~100 more each month. Example asset ID numbers are: ABYZ123456, CDWX789012

For a deployment of this size, choose a 6-digit / 24-bit RAIN CIN length. We'll assume an RFID tag with 128 bits EPC/UII memory, no User Memory, and no XPC features.

First, select the PC Word value for: Length= 8 words ( 128 bits), UMI $=0_{2}, \mathrm{XPC}=\mathrm{O}_{2}, \mathrm{~T}=1_{2}$ AFI=0xAE. From the table, that would be $0 \times 41 \mathrm{AE}$.

We'll assume the assigned CIN from RAIN is 123456, which in hexadecimal is 0x87C440.
With 128 bits EPC/UII memory available, and a RAIN CIN of 24 bits, that leaves 104 bits for my asset data. But, first we have to decide how to store the alphanumeric data in hexadecimal or binary.

One option is to use 8-bit ASCII encoding (https://en.wikipedia.org/wiki/ASCII\#8-bit codes). This approach assigns each number, uppercase and lowercase letter, and some punctuation characters an 8 bit or 2 Hexadecimal character code. Many RAIN RFID readers, printer/encoders, and software tools can convert ASCII characters to hexadecimal for either encoding or reading tag data. There are also many on-line tools available for quick data conversion.

With 10 alphanumeric characters in my asset IDs, converting them to hexadecimal will result in 80 bits or 20 hex characters. But, I have 104 bits of available data, which is enough space for 13 characters. In this example, we'll just pad the original asset IDs with some extra zeros. Another option would be to use a shorter length value in the PC word.

RAIn
ALLIANCE

| ASCII Asset ID | Hexadecimal Asset ID (80 bits) |
| :--- | :--- |
| ABYZ123456 | $0 \times 4142595 A 313233343536$ |
| CDWX789012 | $0 \times 43445758373839303132$ |
|  |  |
| ASCII Asset ID with padded zeros | Hexadecimal Asset ID (104 bits) |
| ABYZ123456000 | $0 \times 4142595 A 313233343536303030$ |
| CDWX789012000 | $0 \times 43445758373839303132303030$ |

Now I can construct the complete EPC/UII:

| PC Word | RAIN CIN <br> Header | Asset ID Hexadecimal | Original Asset <br> ID |
| :--- | :--- | :--- | :--- |
| $0 \times 41 \mathrm{AE}$ | $0 \times 01 \mathrm{E} 240$ | $0 \times 4142595$ A313233343536303030 | ABYZ123456 |
| $0 \times 41 \mathrm{AE}$ | $0 \times 01 \mathrm{E} 240$ | $0 \times 43445758373839303132303030$ | CDWX789012 |

## Example 2.

I run a record keeping system for a large law firm. We need to track more than 1 million documents per year. Our current document IDs are 16 characters long and alphanumeric. Example Document ID numbers are: 1234ABCD-4567EFGH and WXZY1234-QRST5678

For a deployment of this size, choose a 4-digit / 16-bit RAIN CIN length. Example 1 used an 8-bit ASCII encoding scheme, but with 17 characters (including the dash) that would require 152 bits -136 bits for the data and 16 bits for the CIN. While there are tag ICs available with that amount of EPC/UII memory, this example will show how to use Base36 encoding ( https://en.wikipedia.org/wiki/Base36 ) and a more commonly available 128 bit size EPC/UII.

Like example 1, assume an RFID tag with 128 bits EPC/UII memory, no User Memory, and no XPC features will be used. Also assume the assigned 4-digit CIN from RAIN is 1234, which in hexadecimal is 0x8952. Before deciding on the PC Word, we need to determine how to encode the document IDs.

Base36 uses the numbers 0-9 and capital Latin letters A-F. It requires $<6$ bits per character, and for RFID encoding in hexadecimal it works best for data lengths that are a multiple of 8 . In this example we'll encode our 16-digit document IDs in 2 groups of 8 . Conversion between hexadecimal and Base36 is not as widely supported as ASCII by RFID software, but it's a good option encoding scheme for alphanumeric data in RAIN RFID tags.

It's straight forward to convert between Base36 using an on-line tool, excel, or programming script. Each group of 8 Base 36 characters are converted to 12 hexadecimal characters, which takes 96 bits total. With our 16-bit RAIN CIN, that makes the total data length 112 bits. Select the PC Word value for: Length $=7$ words ( 112 bits), $\mathrm{UMI}=\mathrm{O}_{2}, \mathrm{XPC}=0_{2}, \mathrm{~T}=1_{2} \mathrm{AFI}=0 \times \mathrm{AE}$. From the table, that would be 0x39AE.

| PC <br> Word | RAIN CIN <br> Header | Asset ID in Hexadecimal | Document ID in Base36 |
| :--- | :--- | :--- | :--- |
| 0x39AE | 0x04D2 | 0x134D9A27ED 4B9A91D4C1 | 1234ABCD 4567EFGH |
| 0x39AE | 0x04D2 | $0 \times 25916 F 59 E D 0$ 1E8798E0BA4 | WXZY1234 QRST5678 |

When reading the tags, make sure to use the same process in reverse - converting the hexadecimal Asset IDs back into Base36 in the same groups of 12 characters.

## Example 3.

I want to track company IT assets and both a 6-digit alpha numeric asset ID and a 48-bit device MAC address on a 128 bit RAIN RFID tag. I expect to use about 500 tags per year. Examples asset IDs are ABC123 and 789XYZ. Example MAC addresses are 00-14-22-01-2C-45 and 00-40-96-A4-F134.

For a deployment this size, choose an 8 digit / 32-bit CIN length. The 6 -digit asset IDs can be encoded using 8 -bit ASCII with 48 bits, followed by the 486bit MAC address which is already represented in hexadecimal.

Assume we're using a tag with 128 bits of EPC memory, 32 bits of User memory, and no XPC features. Select the PC Word value for: Length $=8$ words ( 128 bits), UMI $=1_{2}, \mathrm{XPC}=0_{2}, \mathrm{~T}=1_{2} \mathrm{AFI}=0 \times \mathrm{AE}$. From the table, that would be 0x45AE.

We'll assume the assigned CIN from RAIN is 12345678, which in hexadecimal is 0x85F1C24E.

| PC <br> Word | RAIN CIN <br> Header | Asset ID + MAC in <br> Hexadecimal | Asset ID | MAC Address |
| :--- | :--- | :--- | :--- | :--- |
| $0 x 45 A E$ | $0 x B C 614 \mathrm{E}$ | $0 \times 414243313233$ <br> $001422012 C 45$ | ABC123 | $00-14-22-01-2 C-$ <br> 45 |
| $0 \times 45 A E$ | $0 x B C 614 \mathrm{E}$ | $0 \times 37383958595 A$ <br> $004096 A 4 F 134$ | 789XYZ | $00-40-96-A 4-\mathrm{F1-}$ <br> 34 |

## Example 4.

I run a logistics business with parcel volume exceeding 100 million packages per year. How can I use the RAIN ISO numbering system to identify packages within my network?

For a deployment this size, choose a 2 digit / 8-bit CIN length. With a commonly available tag with 128 bits of EPC/UII memory, that would leave 120 bits to encode a package IDs. If used efficiently 120 bits can store $2^{120}$ or $1.3 \times 10^{36}$ unique numbers - which is an unfathomably large number!

With the RAIN ISO number system, these 120 bits can be encoded using any method desired. One commonly used approach is to divide the space into sections that represent different attributes. For example, you might choose to segment the EPC/UII data like this:

|  | RAIN CIN | Service Level | Time Stamp | Origin <br> Code | Destination <br> Code | Package <br> Identifier |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Encoded <br> Length | 8 bits | 8 bits | 24 bits | 20 bits | 20 bits | 48 bits |
| Numbers <br> available | 90 | 256 | $\sim 16.7$ million | $\sim 1$ million | $\sim 1$ million | $\sim 280$ trillion |
| Purpose | Identifies <br> tag owner | Freight, <br> Ground, Air, <br> Overnight, <br> Priority, etc. | Identify every <br> minute since <br> $1 / 1 / 2022$ for <br> $\sim 32$ years | Identify every US ZIP | Uniquely <br> identify 280 <br> code, with room to grow | trillion <br> packages |

Again assume we're using a tag with 128 bits of EPC memory, 32 bits of User memory, and no XPC features. From the table select the PC Word value for Length $=8$ words ( 128 bits), UMI=12, $\mathrm{XPC}=0_{2}$, $\mathrm{T}=1_{2}$ and $\mathrm{AFI}=0 \times \mathrm{AE}$, which is $0 \times 45 \mathrm{AE}$. We'll assume the assigned CIN from RAIN is 12 , which in EBV-8 hexadecimal is $0 x 0 C$.

For a package shipped at 8am on October 18, 2022 from Chicago ZIP code 60610 to Denver ZIP code 80202 with service level of 0xA5, example tag data might look like this:

| PC <br> Word | RAIN <br> CIN <br> Header | Service <br> Level | Time <br> Stamp | Origin <br> Code | Destination <br> Code | Package <br> Identifier |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $0 \times 45 A E$ | $0 \times 0 C$ | $0 x A 5$ | $0 \times 066120$ | $0 \times 0 E C C 2$ | $0 \times 1394 \mathrm{~A}$ | $0 \times 123 A B C 456 \mathrm{DEF}$ |

## 2. Frequently Asked Questions

## I encoded ASCII data to my tag, so why is my reader showing me something different?

Most RAIN RFID readers and reader software report tag data in Hexadecimal by default. If you've encoded data using the RAIN ISO numbering system in ASCII, you'll need to convert the data after the CIN header from hexadecimal back into ASCII.

## Why isn't my reader showing me the PC word?

Some RAIN RFID readers and reader software don't show the PC Word by default. Consult with your reader or software provider to make sure they can support filtering tags by the PC Word.

## Why can't I encode a shipping address in an RFID tag?

RAIN RFID tags have limited amount of memory, the most widely used only have $\sim 128$ bits of encodable memory. While that's enough space to uniquely identify a mind-bogglingly large number of items, it's only enough for 16 ASCII characters.

## How do I convert between Decimal, Hexadecimal and Binary?

There are many tools available, including Microsoft Excel conversion functions, the Windows calculator (in programmer mode), or numerous on-line tool

## 3. Table of common PC Word Values using the RAIN AFI

The following table shows valid PC word values in binary and hexadecimal for Toggle Bit =12, $\mathrm{XPC}=0_{2}, \mathrm{AFI}=0 \times A E$, and $\mathrm{UMI}=0_{2}$ or $1_{2}$.

| EPC/UII Length (bits) | UMI $=0$ |  | UMI $=1$ |  |
| :---: | :---: | :---: | :---: | :---: |
|  | PC Word (Binary) | PC Word (Hexadecimal) | PC Word (Binary) | PC Word (Hexadecimal) |
| 0 | 00000001 | 01AE | 00000101 | 05AE |
| 16 | 00001001 | 09AE | 00001101 | ODAE |
| 32 | 00010001 | 11AE | 00010101 | 15AE |
| 48 | 00011001 | 19AE | 00011101 | 1DAE |
| 64 | 00100001 | 21AE | 00100101 | 25AE |
| 80 | 00101001 | 29AE | 00101101 | 2DAE |
| 96 | 00110001 | 31AE | 00110101 | 35AE |
| 112 | 00111001 | 39AE | 00111101 | 3DAE |
| 128 | 01000001 | 41AE | 01000101 | 45AE |
| 144 | 01001001 | 49AE | 01001101 | 4DAE |
| 160 | 01010001 | 51AE | 01010101 | 55AE |
| 176 | 01011001 | 59AE | 01011101 | 5DAE |
| 192 | 01100001 | 61AE | 01100101 | 65AE |
| 208 | 01101001 | 69AE | 01101101 | 6DAE |
| 224 | 01110001 | 71AE | 01110101 | 75AE |
| 240 | 01111001 | 79AE | 01111101 | 7DAE |
| 256 | 10000001 | 81AE | 10000101 | 85AE |
| 272 | 10001001 | 89AE | 10001101 | 8DAE |
